JOB COMPLETION REPORT

RESEARCH PROJECT SEGMENT  
(Inventory)

State of UTAH

Project No. W-65-R-D-22

Project Title: State-wide Wildlife Management Inventory

Job No. A-4

Job Title: State-wide Upland Game Inventory and Management

Period Covered: January 1, 1973 to June 30, 1974

Abstract: This report includes upland game inventory and harvest data relating to the 1973-74 hunting seasons. Results of annual inventory and harvest surveys and long-term trends of indexes derived by each method are included. Data obtained in 1973 are compared to 1972 and long-term averages.

Objectives: To conduct annual inventories and determine the population trend and annual harvest of upland game.

Procedures: Annual inventory procedures for ring-necked pheasants included winter sex-ratio counts and summer roadside counts. The winter sex-ratio counts were conducted from December 15, 1972, through February 10, 1973, as snow cover conditions allowed. Indexes derived include hen-cock ratios and pheasants observed per 100 hours. Annual summer roadside counts (three or more per route) were conducted from July 22 - August 3 on permanently established routes. Indexes derived include pheasants per mile, young per mile, young per hen, mean brood and percent of hens with young.

Mourning dove breeding population trend was determined via the annual call-count survey. This survey is part of a nation-wide survey administered by the Bureau of Sport Fisheries and Wildlife. Call-counts are conducted over 15 permanent, 20-mile routes. One count was made on each route between May 20-30. Doves were banded during the preseason banding period (June 1 - August 20) primarily using mist nets at waterholes.

Random brood counts were conducted on chukar and Hungarian partridge, forest grouse (ruffed and blue), sage grouse, wild turkey and quail from July 10-August 5. Indexes derived for each species include mean brood size, young per 100 adults and birds observed per 100 hours effort.

Sage grouse strutting ground counts were conducted from March 15-May 15. Total cocks counted, average cocks per ground and percent change from 1972 for comparable grounds were determined on a county basis.

One Gambel's quail call-count route was run in Washington County in late April and early May. Long-period waterhole counts were completed in July and August.

Cottontail rabbit roadside counts were conducted over pre-established routes between July 15 and August 5. Indexes derived include rabbits per mile and young per 100 adults.

Two separate harvest questionnaires were mailed to an approximate 11 percent sample of eligible licensees. One, concerning the harvest of game birds excluding wild turkeys, was mailed in January 1974, and the other concerning cottontails was mailed following the close of the season in March 1974. Questions were asked concerning the number harvested and the number of days hunted in each county by species. Additional questions were asked of cottontail hunters concerning harvest by month and whether or not they hunted upland game birds in 1973. A separate questionnaire was also sent to all wild turkey permittees following the close of the spring season. Upland game bird and cottontail rabbit questionnaires were processed by the University of Utah Computer Center and turkey questionnaires by Game Management Section personnel. Total harvest, hunters and hunter-days afield were estimated using standard projection factors based on total eligible licensees and total questionnaire returns. Hunter success per day and per hunter was determined as well as the distribution of harvest and hunting pressure by county.

Field bag checks of upland game hunters were made at random or at checking stations during each hunting season. Indexes derived include bag per hunter (per day), bag per 100 hours, average hours per hunter-day and average hours per bird bagged.

Recommendations:

This project should be continued for the purpose of determining trends of upland game inventory and harvest statistics in Utah.

Merle V. Hancock  
Chief, Game Management

Jan King  
Federal Aid Coordinator

Date:

August 6, 1974

# INTRODUCTION

The objective of Utah's upland game management program is to provide recreational hunting opportunity for sportsmen within the limits of the annual harvestable surplus for each species. It is based on the knowledge that populations of upland game experience relatively high rates of annual turnover. High reproductive rates are naturally compensated for by high death rates, whether hunting is allowed or not. Annual surveys are conducted to measure the production, trend and harvest of each upland game population hunted.

This is the third edition of this annual Upland Game Report. It is a consolidation of, and annual completion report for, information compiled during all inventory and harvest surveys conducted under Federal Aid Project, W-65-R, Job A-4. Information contained herein was compiled by conservation officers, biologists and game managers of the Division of Wildlife Resources. Harvest information previously published in the annual Upland Game Harvest Book is included.

This report serves as a handbook of inventory and harvest trend data. It is designed primarily for the use of those concerned with the management of upland game in Utah. A separate section is devoted to each form of upland game hunted in Utah. Data is presented primarily in tabular form with limited narrative comment. The first page of each section provides a brief summary of population status and trend as indicated by inventory and harvest data.

During 1973, a total of 92,098 Utah sportsmen spent 606,925 days afield in pursuit of various upland game species. The harvest of upland game totaled 719,308. The proportion of the total upland game hunters which pursued each species is shown in Appendix Table 2 and the percentage failing to bag at least one bird of each species in Appendix Table 3. The framework for 1973 upland game hunting seasons is shown in Appendix Table 4. Harvest statistics by species were as follows:

Species	Hunters Afield	Total Harvest	Hunter Days	Bag/Hunter-day	Bag/Hunter for Season
Pheasant	75,968	196,012	278,033	0.70	2.58
Mourning dove	27,435	307,062	97,788	3.14	11.19
Chukar partridge	13,888	48,135	50,677	0.95	3.47
Sage grouse	10,017	13,926	19,049	0.73	1.39
Forest grouse	17,588	45,232	44,738	1.01	2.57
Quail	5,654	14,324	17,777	0.81	2.53
Hungarian partridge	3,566	6,014	11,516	0.52	1.69
Wild turkey					
spring	135	0	311	0.00	0.00
fall - no season					
Cottontail	20,109	88,603	87,036	1.02	4.41

Total hunters afield for all species of upland game birds = 85,986

Hunters afield for cottontails who did not hunt game birds = 6,112

Total upland game hunters afield = 92,098

---

The harvest of game birds was based on a 45.5 percent return of 17,572 questionnaires and cottontail harvest data on a 34.7 percent return of 17,020 questionnaires.

Weather conditions during the early part of 1973 were almost the exact opposite of 1972, especially in the southern one-half of the State, where the first quarter of the year was the driest in history. Weather conditions in 1973 were characterized by near record snow and cold in January and well below normal temperatures during most of February, March and April. This delayed the development of most agricultural crops and probably had a similar effect on upland game species. Early summer was unusually wet in southern and eastern counties but was relatively dry in the northern mountains and along the Wasatch Front. The pattern reversed during July with above normal moisture in the north and dry weather in the south. Temperatures were above normal in May and continued that way through August. In September a cold front brought heavy precipitation in the north and below normal temperatures over most of the State. The opening weekend of the mourning dove season was wet and cool. Warm, dry weather prevailed through October and into November. The opening of the pheasant season was warm and dry but later in November above normal precipitation occurred statewide. December had relatively dry weather except in the northern mountains and along the Wasatch Front. Temperatures for the year were generally normal or below while precipitation accumulations were above normal, especially along the Wasatch Front.

It is probably that the heavy winter snows proved detrimental to most species and tended to depress breeding population levels. The late spring was harmful to the production of pheasants and California quail, while most other species seemed to benefit from the added moisture and improved forage conditions.

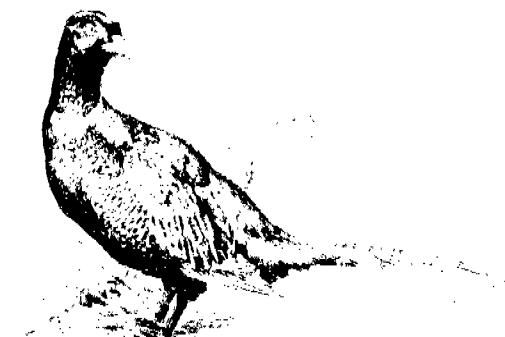

# RING-NECKED PHEASANT

## SUMMARY

The fall pheasant population in 1973 dropped to what was probably its lowest level in several decades. This was the result of a combination of generally below average production since 1968 and gradually deteriorating habitat. The greatest reduction in pheasant density has occurred in the more intensely farmed areas of the Northern Region and in the Southeastern Region.

The breeding population was lower than in 1972; however, such a decrease was not reflected in sex-ratio counts due to concentration of pheasants and resultant greater counting efficiency. Production improved in the Northern, Northeastern and Southeastern regions to near normal but decreased in the Central and Southern regions resulting in a statewide index similar to 1972 but slightly below average.

Harvest statistics reflected the decreased population level as hunting pressure, harvest and hunter success all declined. Total hunters and hunter success per day were the lowest on record. Reduced hunter participation resulted primarily from reduced bag and possession limits and an advertised reduction in pheasant abundance. Bag and possession limits were reduced from 3 and 6 to 2 and 4 respectively. Weather conditions for the opening weekend of the season were generally warm and dry.

### Winter Sex-ratio Counts

Results of this survey for the winter of 1972-73 and long-term trends are shown in Tables 1 and 2 of this section. Comparisons to the winter of 1971-72 and the average on a statewide basis are as follows:

	<u>Winter of 1972-73</u>	<u>Percent change from 1971-72</u>		<u>Average</u>
Total pheasants counted (roadside)	14,758	+27	-7	
Hens per cock	5.6	+14	+33	
Pheasants observed per 100 hours	1,692	+9	-5	
Total hours effort (roadside)	953	+28	+17	

Total sample size was about one-fourth greater than in 1972 but still slightly below average. Pheasants observed per 100 hours effort was higher than 1972 but below average.

The above suggests an increased breeding population level for 1973 which is not in concert with the reduced harvest and hunter success of 1972. It is probable that the relatively severe winter of 1972-73 concentrated pheasants facilitating increased counting efficiency. The 1973 breeding population level was probably lower than 1972. Hen-cock ratios were wider than both 1971-72 and the average reflecting both greater hunting pressure in 1972 and counting conditions. Assuming a preseason sex ratio of 1.1 hens per cock, hunters harvested approximately 80 percent of the 1972 fall population.

### Roadside Counts

A summary of pheasant roadside counts for 1973 is shown in Table 3. Long-term trends of pheasants per mile, young per mile, young per hen, percent of hens with young and mean brood size are found in Tables 4-8. Survey results for 1973 compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>		<u>Average</u>
Total pheasants observed	1,894	-53	-54	
Total miles driven	2,561	-15	-9	
Pheasants per mile	0.74	-44	-51	
Average brood size	5.65	+1	+3	
Young per hen	3.95	+1	-7	
Percent of hens with young	74	+3	-3	

Indicated pheasant density was only about one-half that of both 1972 and the average. Because of a late spring, grain and second-crop hay were not harvested by the survey period, resulting in poor counting conditions. This probably biased density indexes downward. Production statewide was similar to 1972 and only slightly less than average. Production improved in the Northern, Northeastern and Southeastern regions to near average. Fall pheasant populations appeared to be down from 1972 but probably not to the degree indicated by the pheasants per mile index. The decline was primarily attributable to a reduced breeding population level.

HarvestHunter Questionnaire

Results of the hunter questionnaire for 1973 are shown in Table 9. Long-term trends of pheasants bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county are found in Tables 10-12 and total statewide harvest statistics in Table 13. Following is a comparison of 1973 harvest statistics to 1972 and the average:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Pheasant hunters	75,968	-10	-10
Pheasants harvested	196,012	-18	-22
Hunter-days afield	278,033	-15	+34
Pheasants per hunter	2.58	-9	-13
Pheasants per hunter-day	0.70	-4	-42

In 1973, the daily bag limit was reduced from 3 to 2 and the possession limit from 6 to 4. This, coupled with an advertised reduction in pheasant abundance, resulted in only 75,968 hunters afield, the lowest number of hunters on record. The number of hunter-days afield also declined from 1972 but was well above average due to the relatively long season (up to 30 days). Total harvest and hunter success declined as expected because of the reduced bag limit and fewer pheasants. Weather conditions were generally warm and dry on the opening weekend of the hunting season (November 10 and 11).

Long-term trends (1948-73) of total pheasant hunters, harvest and hunter success are shown in Figure 1.

Field Bag Checks

A summary of pheasant field bag check data for 1973 is shown in Table 14. The hunter success trend determined via bag check since 1966 is found in Table 15. A comparison of 1973 data on a statewide basis to 1972 and the average follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Total hunters checked	6,957	+57	+83
Total hours hunted	24,043	+47	+79
Pheasants per hunter (complete hunts)	0.70	-15	-32
Pheasants bagged per 100 hours	14	-12	-36
Average hours per hunter-day (complete hunts)	4.4	-12	-8
Hours hunted per pheasant bagged	6.3	+3	+34

Hunter success indicated by this survey for 1973 was the lowest recorded since it was initiated in 1966. The statewide index of 0.70 pheasants bagged per hunter-day was identical to that derived via questionnaire.

The average hunter checked spent 4.4 hours per day afield, a decrease from both 1972 and the average. Slightly more hours were required to bag one pheasant.

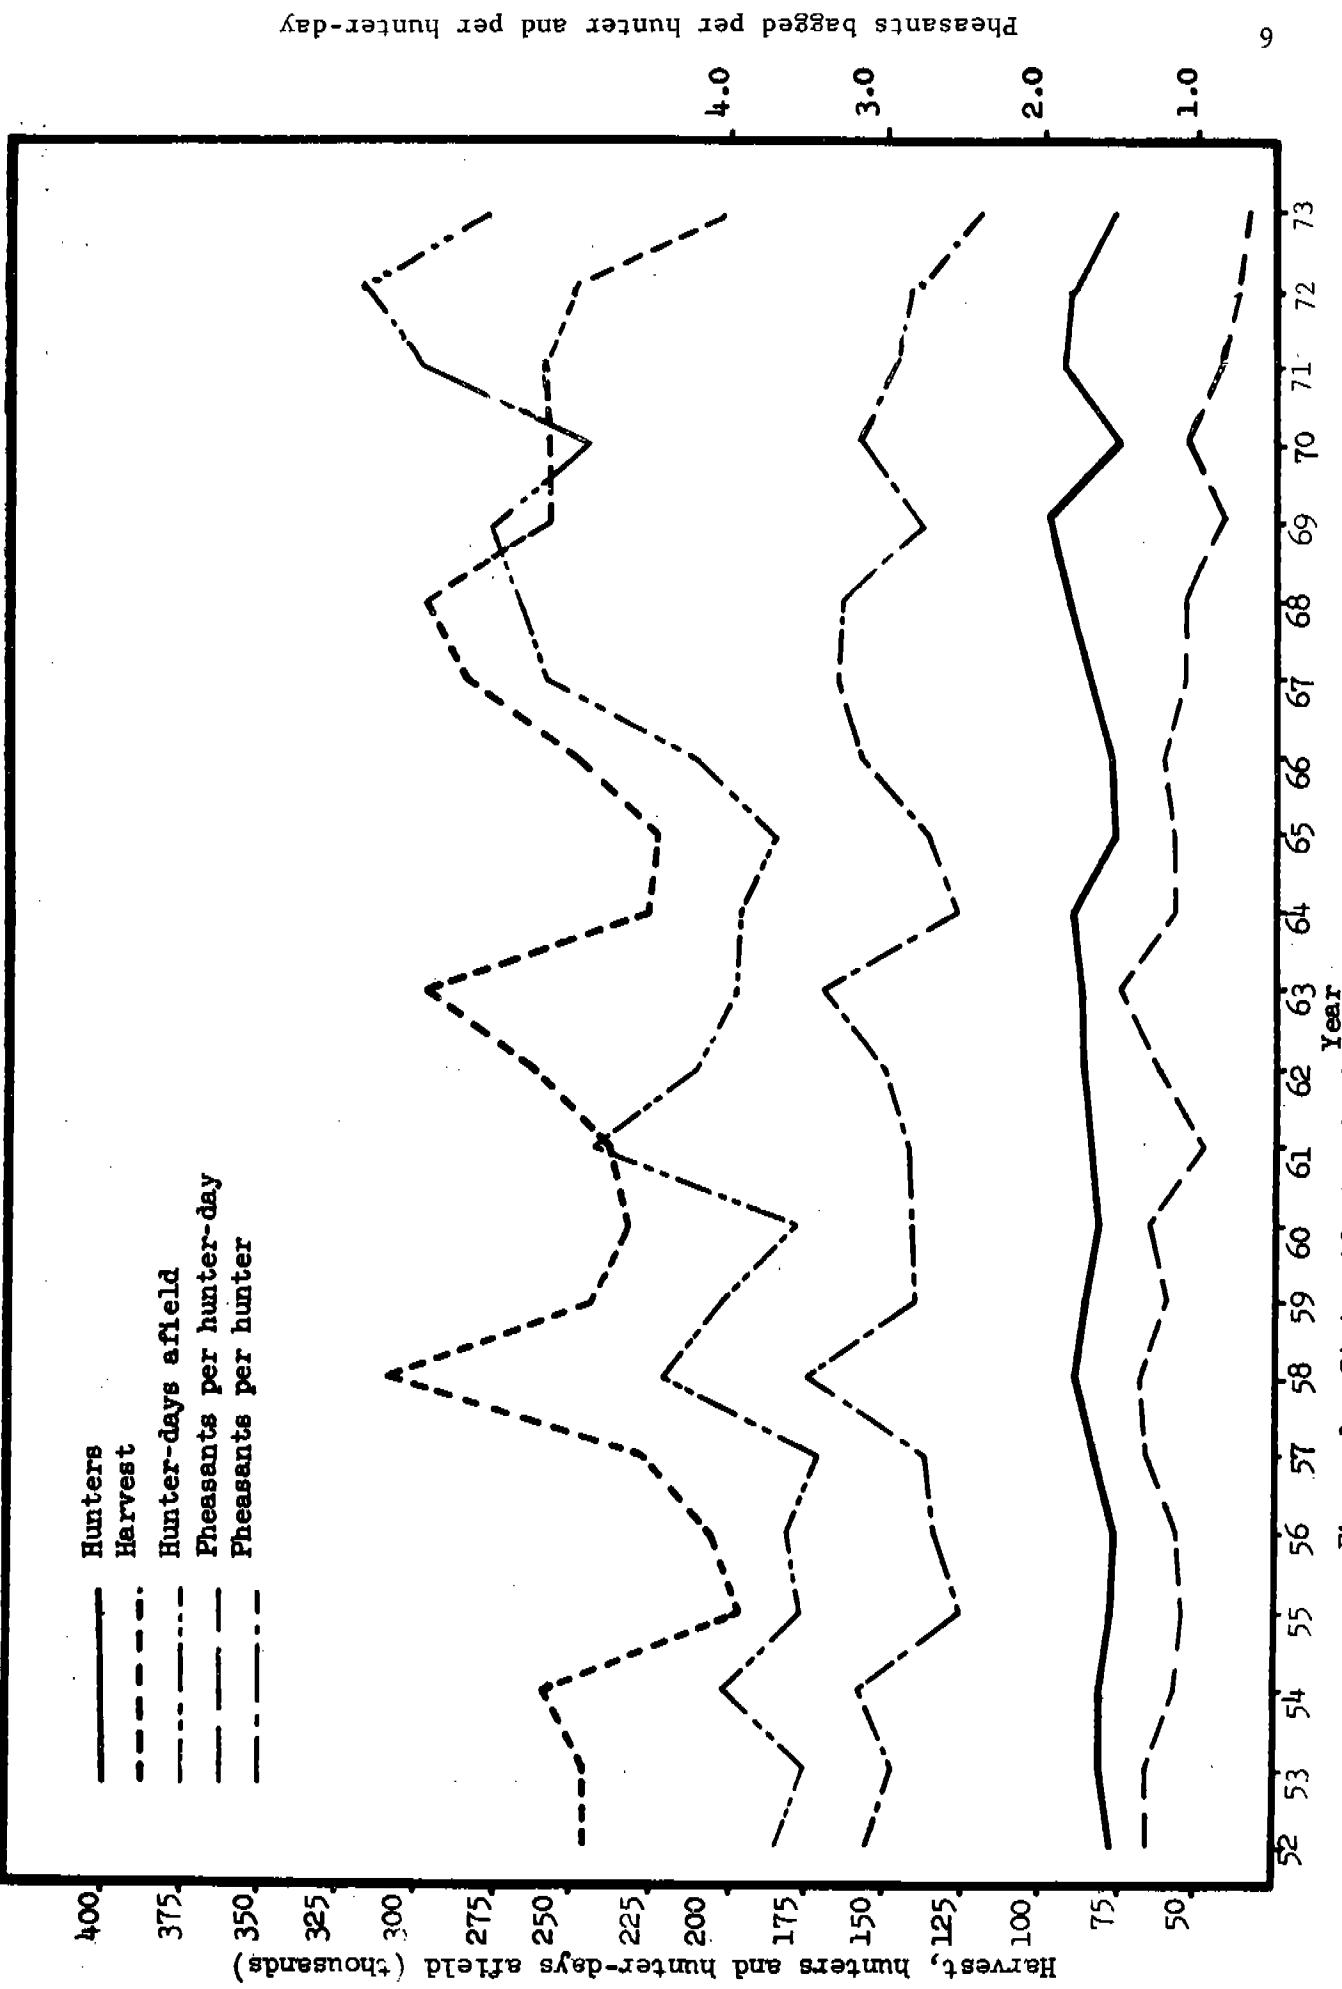

Figure 1. State-wide trend of pheasant harvest statistics.

Table 1. Summary of pheasant winter sex-ratio counts, 1972-73.

# MOURNING DOVE

## SUMMARY

The breeding density index (BDI) derived from the annual call-count survey indicated a slight decline from both 1972 and the average, but this was possibly biased downward by the late spring and resultant delayed nesting. Banding data suggested increased production.

Hunters declined slightly but total hunter-days increased, as did hunter success, resulting in a record harvest of 307,062 mourning doves.

Mourning dove banding efforts netted only 755 doves in 1973 of which 51.4 percent were immatures and 48.6 percent adults.

### Call-Count Survey

Results of the 1973 call-count survey are found in Table 1 of this section. The long-term trend of the State's Breeding Density Index (average doves heard per route) is shown in Table 2. Indexes shown in each of these tables are unweighted and consequently differ somewhat from those published in the annual Mourning Dove Status Report compiled by the Bureau of Sport Fisheries and Wildlife. Indicated trends are similar. Following is a comparison of the results of the 1973 survey to 1972 and the average for the period 1964-72:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total doves heard per route	12.8	-10	-7
Total calls heard per route	46.3	-17	-33
Total doves seen per route	4.5	-48	-75

The breeding density index was down slightly from both 1972 and the average, possibly due to the late spring and delayed nesting.

The long-term trend of Utah's dove population as shown in the Mourning Dove Status Report for 1973 is downward but not to a degree that is statistically significant. The trend since 1964 as shown in Table 2 is relatively stable. It is probable that habitat deterioration over the past several years has had a detrimental influence upon the State's dove population.

### Harvest

#### Hunter Questionnaire

Information obtained from the hunter questionnaire for 1973 is summarized in Table 3. Long-term trends of mourning doves bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county are found in Tables 4-6 and total State-wide harvest statistics in Table 7. Harvest statistics for 1973 compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Mourning dove hunters	27,435	-6	+66
Mourning dove harvest	307,062	+29	+108
Hunter-days afield	97,788	+4	+107
Mourning doves per hunter	11.19	+38	+29
Mourning doves per hunter-day	3.14	+24	-17

Weather conditions during August consisted of near normal temperature and slightly below normal precipitation. The week preceding the opening of the dove season was generally dry with but few scattered showers and minimum temperatures in the mid-forties and fifties. The opening weekend of the season (September 1, 2) was marked by rain showers in the north but relatively dry weather in the south. The inclement weather did not seem to hamper dove hunting.

Results of the harvest questionnaire showed a slight decrease in total hunters, possibly attributable to stormy weather in the north, but a marked increase in total hunter-days afield. The increased total days was probably a response to improved hunter success. The total harvest of 307,062 doves was an all-time record as was the number of doves bagged per hunter for the season. Success per hunter-day was considerably higher than 1972 but still below average.

Long-term harvest trends are depicted in Figure 1.

#### Field Bag Checks

A summary of field bag check data for 1973 is shown in Table 8. Hunter success trends determined via this method are shown in Table 9. Results of the 1973 survey compare to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total hunters checked	1,329	+4	-3
Total hours hunted	3,704	+10	-2
Doves per hunter (complete hunts)	3.51	+16	+1
Doves bagged per 100 hours	126	+46	+34
Average hours per hunter-days (complete hunts)	3.6	+12	+3
Hours hunted per dove bagged	1.0	-17	-9

Hunter success shown by field bag checks in 1973 was somewhat higher than in 1972, consistent with the increased success shown by questionnaire data, but indicated better success than did the questionnaire. This is probably attributable to the fact that bag check data is compiled primarily on the opening weekend when hunting is at its best success-wise.

Dove hunters spent slightly more time afield per day than in 1972 but less time was required to bag a dove.

#### Banding

Results of the annual preseason mourning dove banding program for 1973 are shown in Table 10. The trend of doves banded since 1961 is shown in Table 11. Band recovery rates and distribution of recoveries by State and country for Utah banded doves are shown in Tables 12 and 13 respectively. Table 14 is a summary of the number of doves banded in other states that have been recovered in Utah.

During 1972, only 755 doves were banded in Utah, all by Division personnel. Banding was distributed among nine counties.

Age composition of doves banded was 51.4 percent immatures and 48.6 percent adults. This suggests increased reproductive success in 1973 as compared to 1972 when 36.9 percent of the doves banded were immatures.

The direct recovery rate or the percentage of doves killed during the first hunting season following banding for immatures and adults combined from 1949-62 was 1.1 percent. From 1964-71 this value was 1.4 percent. Total recovery rate (direct recoveries plus all subsequent recoveries) for both periods, was 2.7 percent. Expansion of the direct recovery rate of 1.4 percent for the period 1964-71 using an assumed band reporting rate of 30 percent indicates that only 4.7 percent of the State's mourning doves were harvested by hunters during this period. If crippling loss is considered, the total death rate due to hunting would still not exceed 5-10 percent of the population.

The distribution of band recoveries for Utah banded doves shows that 78.6 percent of combined recoveries (including recoveries, returns or foreign retraps) have been made in Utah. Recoveries from Utah and apparent primary dove wintering areas in Arizona, California and Mexico combined account for 97.7 percent of all recoveries received as of March 31, 1972.

Only 31 bands have been recovered in Utah from doves banded in other states. Of this number, 14 were originally banded in Arizona, primarily during the winter months.

In summary, it is evident that Utah hunters primarily harvest doves that are raised in Utah. They do not harvest a significant number of migrating doves. Doves produced in Utah, but harvested elsewhere, are probably not harvested while migrating, but rather on the wintering area indicating rapid movement from summer to winter habitat.

## **SUMMARY**

Harvest data for the 1972 hunting season indicated a reduced breeding population level for 1973. Brood counts yielded fewer chukars than average but indicated production was good, suggesting increased chukar abundance in the fall.

Harvest questionnaire data reflected the increased production as both total harvest and hunter success increased. The number of hunters declined, apparently in response to reduced bag limits and poor success in 1972, but those going afield spent more total hunter-days than in 1972. Bag and possession limits were reduced from 8 and 16 to 5 and 10 respectively.

Hunter success indexes derived from field bag checks were contradictory with one (chukars/100 hours) showing increased success and the other (chukars/hunter) showing a slightly decreased success rate. Hunters checked spent fewer hours afield than in 1972. Less time was required to bag one chukar than in 1972 but slightly more than average. It is evident that the improved production of 1973 resulted in an increased fall population level.

### Brood Counts

Results of the annual random brood survey for 1973 are shown in Table 1 of this section. Long-term trends of young-adult ratios, mean brood size and chukars observed per 100 hours are found in Tables 2-4. Survey results for 1973 compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total chukars observed	545	-75	-67
Young per 100 adults	519	+121	+26
Mean brood size	10.65	+6	+20
Chukars observed per 100 hours	150	-73	-71
Total hours effort	363	-6	-8

Low hunter success and harvest during 1972 indicated a decreased breeding population level for 1973.

Accumulated moisture levels were high during the late-winter and spring of 1972-73 and consequently forage conditions were good. As a result, production was high with a 121 percent increase in young per adult over 1972 and 26 percent over the average.

Less time was devoted to chukar brood counts in 1973. Additionally, because of generally abundant forage and slightly below normal temperatures in July chukars did not seem to concentrate around water. These two factors were apparently responsible for a substantial decrease in chukars observed during brood counts as well as the number observed per 100 hours effort.

### Harvest

#### Hunter Questionnaire

Results of the hunter questionnaire survey for 1973 are shown in Table 5. Long-term trends of chukars bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county are found in Tables 6-8 and total State-wide harvest statistics in Table 9. Following is a comparison of 1973 harvest statistics to 1972 and the average:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Chukar hunters	13,888	-17	-13
Chukars harvested	48,135	+30	+12
Hunter-days afield	50,677	+9	+14
Chukars per hunter	3.47	+57	+46
Chukars per hunter-day	0.95	+20	+4

The daily bag limit for chukars was decreased from 8 to 5 and the possession limit from 16 to 10 for the 1973 season. This, in combination with the relatively poor success of 1972, was apparently responsible for a reduction in chukar hunters afield. Those who hunted chukars found improved success in the Northern, Central and Southeastern regions with the result being an increased number of hunter-days afield. Total harvest and hunter success, per day and for the season, increased over both 1972 and the average.

Long-term trends of chukar harvest statistics are shown in Figure 1.

#### Field Bag Checks

A summary of field-bag-check data for 1973 is shown in Table 10. The hunter success trend determined via bag check since 1966 is shown in Table 11. Data for the 1973 season compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Total hunters checked	401	-30	-49
Total hours hunted	1,857	-47	-50
Chukars per hunter (complete hunts)	0.91	-6	-21
Chukars bagged per 100 hours	17	+21	-32
Average hours per hunter-day (complete hunts)	4.9	-26	+2
Hours hunted per chukar bagged	5.4	-29	+9

Field bag check sample sizes were poor in most counties. Total hunters checked statewide was down considerably from both 1972 and the average. Hunter success per 100 hours effort increased over 1972, in concert with the questionnaire, but success per day (where sample sizes were lowest) showed a slight decrease from 1972.

The average hunter spent fewer hours afield per day than in 1972 but slightly more than average. Less hours were spent per chukar bagged than in 1972 but still more than average.

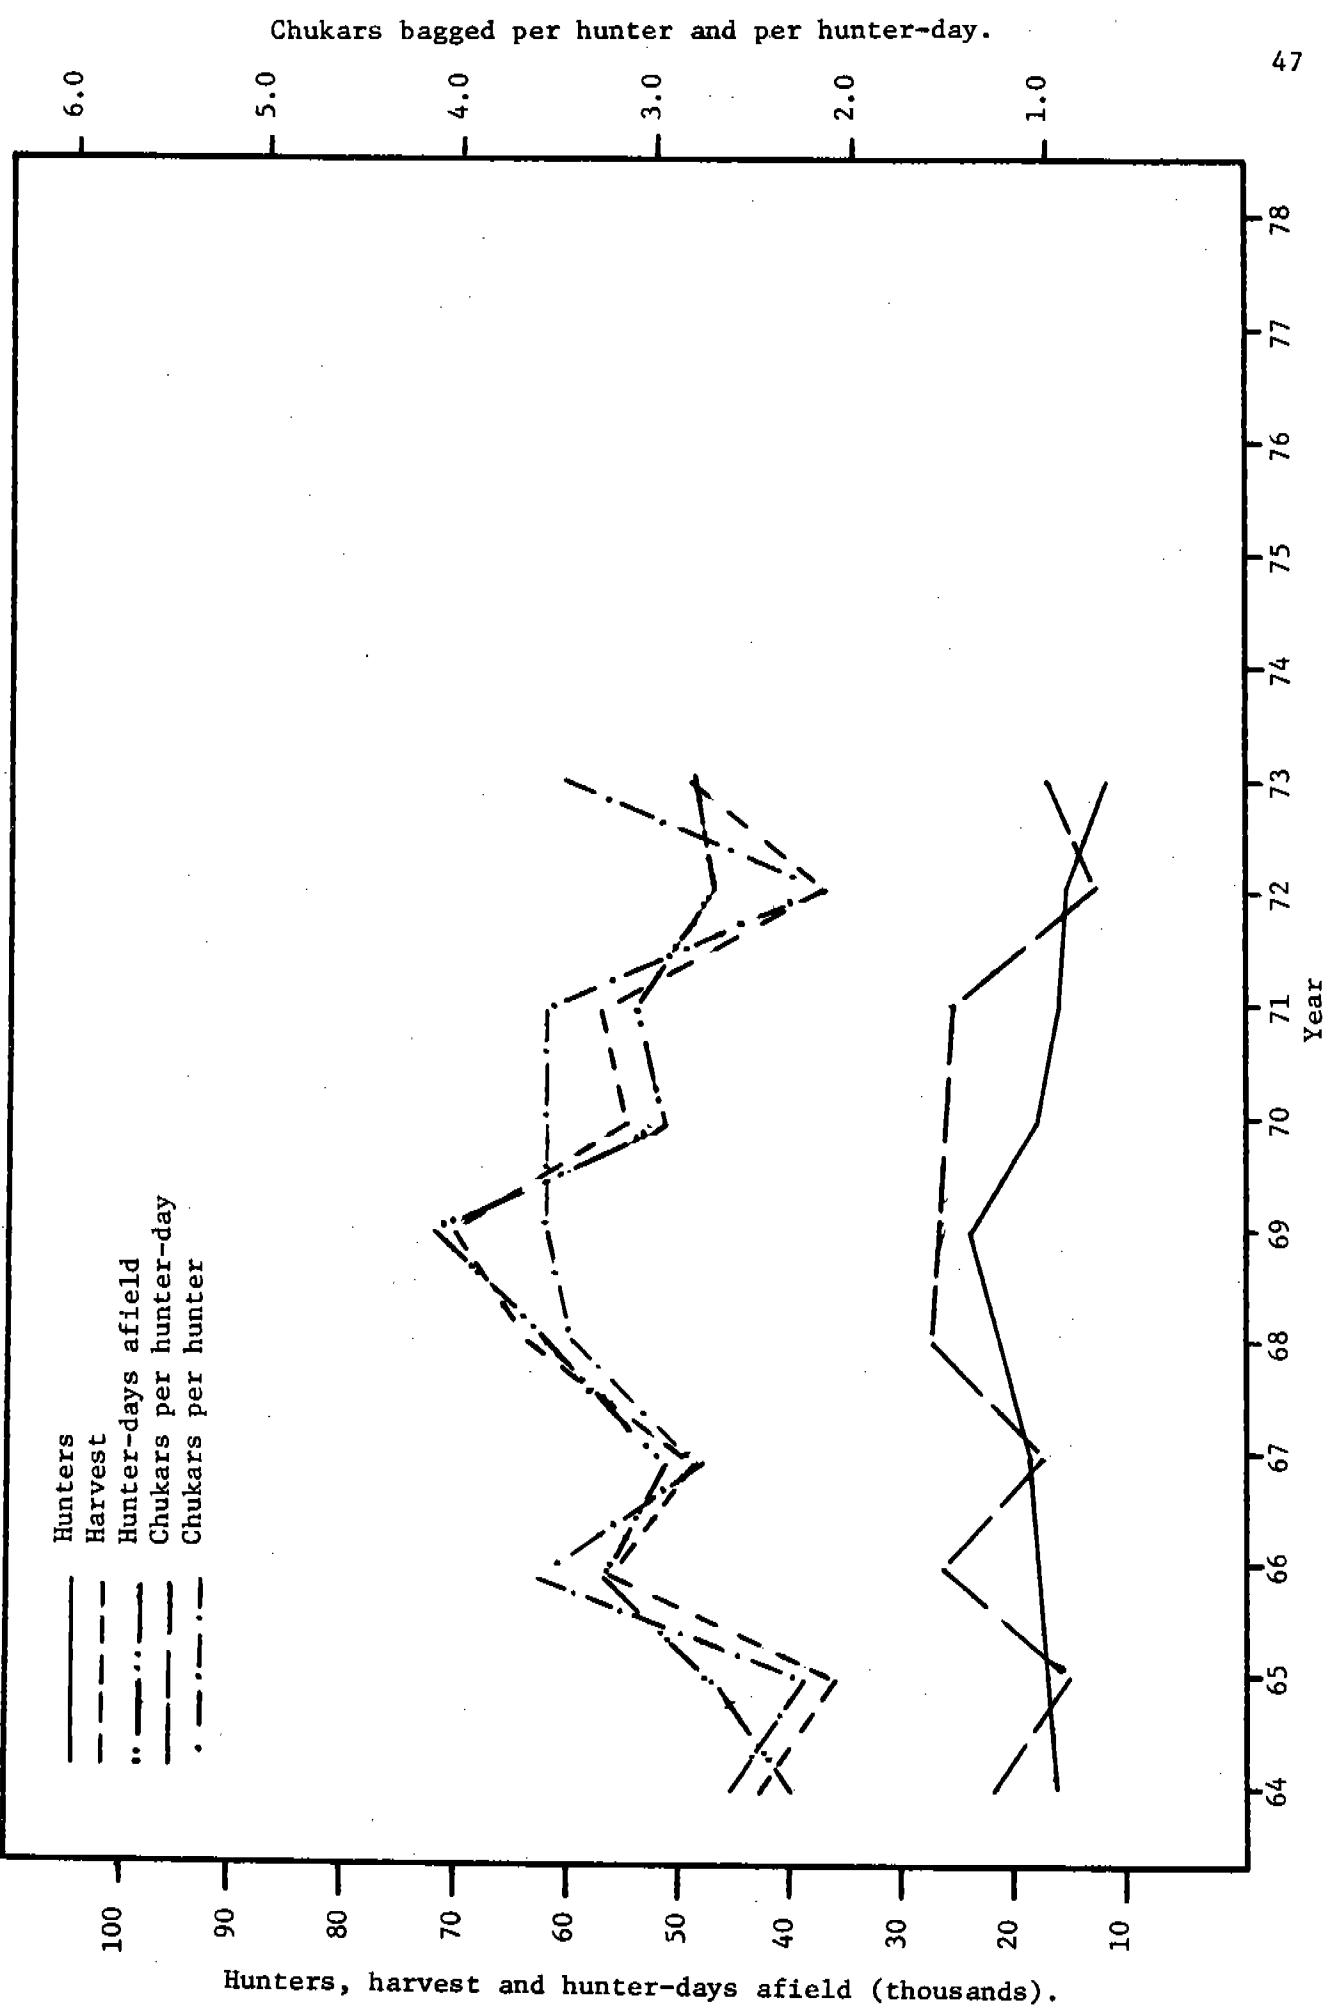

Figure 1. Statewide trends of chukar partridge harvest statistics.

# SAGE GROUSE

## SUMMARY

Harvest data for 1972 and strutting ground counts indicated a decreased breeding population level for 1973. Production indexes increased over 1972 with the highest young-adult ratio recorded since 1965. The fall population was estimated to be equal to or slightly higher than 1972.

During the 1973 hunting season fewer hunters went afield than in 1972 and harvested less sage grouse. The decreased harvest was solely a result of less hunting pressure as hunter success, as indicated by both the questionnaire and field bag checks, increased slightly over 1972.

It appears that the downward trend since 1969 was stabilized in 1973 or possibly even somewhat reversed.

### Strutting Ground Counts

The status of the sage grouse breeding population for 1973 as indicated by strutting ground counts is shown in Table 1 of this section. Results of this survey for 1973 compared to 1972 and the 1967-72 average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Number of grounds counted	108	-4	+156
Total grouse counted	1,809	-27	+74
Average male grouse per ground	16.8	-23	-27
Percent change from previous year (comparable grounds)	-26	--	--

Reduced hunter success and harvest in the fall of 1972 indicated a reduced breeding population level for 1973. Strutting ground counts reflected such a reduction. Poor counting conditions resulting from the late spring and inaccessibility of some strutting grounds probably biased counts downward, possibly exaggerating the degree of decline.

### Brood Counts

Results of this survey for 1973 are found in Table 2. Long-term trends of young-adult ratios, mean brood size and sage grouse observed per 100 hours are shown in Tables 3-5. Indexes for 1973 compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Total sage grouse counted	2,120	-38	-30
Young per 100 adults	195	+95	+34
Mean brood size	4.58	+10	+1
Sage grouse observed per 100 hours	237	-36	-36
Total hours effort	895	-3	+10

Conservation officers spent slightly less time than in 1972. Considerably fewer grouse were counted. The density index (grouse per 100 hours) was probably biased downward due to good moisture and vegetative conditions and resulting less concentration of birds. Production increased substantially over both 1972 and the average. The 195 young per 100 adults ratio indicated the best production since 1965 and suggests a stabilization of the current downward trend and possibly even a slight increase.

### Harvest

#### Hunter Questionnaire

Results of the 1973 hunter questionnaire are shown in Table 6. Long-term trends of sage grouse bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county are found in Tables 7-9 and total statewide harvest statistics in Table 10. The 1973 hunting season compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Sage grouse hunters	10,017	-23	+14
Sage grouse harvested	13,926	-13	+17
Hunter-days afield	19,049	-14	+42
Sage grouse per hunter	1.39	+13	+4
Sage grouse per hunter-day	0.73	+1	-19

Harvest information indicated a population level comparable to or possibly slightly higher than in 1972. Total hunters declined 23 percent while total harvest only dropped 13 percent. Hunter success per day was similar to 1972, with less liberal bag limits in some areas, while success for the season increased.

Long-term sage grouse harvest trends are shown in Figure 1.

#### Field Bag Checks

A summary of field-bag-check data for 1973 is shown in Table 11. Hunter success trends determined via this method since 1966 are shown in Table 12. Results of the 1973 survey compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Total hunters checked	1,910	-23	-5
Total hours hunted	7,287	-31	-12
Sage grouse per hunter (complete hunts)	0.73	+3	-13
Sage grouse bagged per 100 hours	17	+13	-15
Average hours per hunter-day (complete hunts)	4.0	-13	+3
Hours hunted per grouse bagged	5.6	-19	+8

Hunter success (per day) shown by this survey was identical to that shown by questionnaire and slightly higher than 1972 but below average. The average hours per hunter-day index was lower than 1972, but slightly higher than average. Less time was required for each grouse bagged in comparison to both 1972, but slightly more than average.

Sage grouse bagged per hunter and per hunter-day.

62

# FOREST GROUSE

## SUMMARY

The breeding population level in 1973 for both ruffed and blue grouse was probably similar to 1972. Production of ruffed grouse was lower than both 1972 and the average while blue grouse showed improved production. Sample sizes of brood data were low, especially for ruffed grouse. Fall populations were considered to be down for ruffed grouse and no better than comparable to 1972 for blue grouse.

Harvest data showed a 65 percent decline in ruffed grouse harvested, while blue grouse harvested almost double. The net result was a record harvest of 45,232 forest grouse. The increased harvest was a direct result of increased hunters and hunter-days afield. Hunter success declined slightly indicating a lower fall population level than in 1972. Hunters spent less time hunting per day and more time for each grouse bagged.

Brood CountsRuffed Grouse

Results of the annual random brood survey for 1973 are shown in Table 1 of this section. Long-term trends of young-adult ratios, mean brood size and ruffed grouse observed per 100 hours are found in Tables 2-4. A summary of effort expended on ruffed and blue grouse brood counts combined is shown in Table 9. Survey results for 1973 compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Total ruffed grouse observed	155	-30	-53
Young per 100 adults	297	-23	-6
Mean brood size	4.58	-1	-3
Ruffed grouse observed per 100 hours	18	-36	-65
Total hours effort (Forest grouse)	880	+10	+35

Harvest statistics for 1972 indicate an above average breeding population of ruffed grouse for 1973.

Hours effort on forest grouse brood counts increased over 1972 but the number of ruffed grouse observed decreased. The number observed per 100 hours effort decreased substantially from both 1972 and the average. Indicated production was considerably lower than 1972 and slightly below average, however, sample sizes were not sufficient to be accurate. It was assumed, based on the limited data available that ruffed grouse numbers were down.

Blue Grouse

Results of the annual random brood survey for 1973 are shown in Table 5 of this section. Long-term trends of young-adult ratios, mean brood size and blue grouse observed per 100 hours are found in Tables 6-8. Survey results for 1973 compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Total blue grouse observed	580	-23	+10
Young per 100 adults	237	+6	-16
Mean brood size	4.81	+4	+3
Blue grouse observed per 100 hours	66	-30	-20
Total hours effort (Forest grouse)	880	+10	+35

Harvest statistics for 1972 indicated that the breeding population was at an average level in 1973.

Total blue grouse observed during brood counts was less than 1972 but above average while the number observed per 100 hours was less than both 1972 and the average. Indicated production was better than in 1972 and similar to or slightly below average. The fall population was probably similar to or lower than 1972.

HarvestHunter Questionnaire

Results of the 1973 forest grouse (ruffed and blue grouse combined) hunter questionnaire are shown in Table 10. Long-term trends of forest grouse bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county are found in Tables 11-13 and total statewide harvest statistics in Table 14. Harvest statistics for 1973 compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Forest grouse hunters	17,588	+6	+50
Forest grouse harvested	45,232	+6	+101
Hunter-days afield	44,738	+15	+114
Forest grouse per hunter	2.57	+0.4	+25
Forest grouse per hunter-day	1.01	-7	-5
Percent ruffed grouse	15.8	-67	-67
Percent blue grouse	81.4	+80	+83
Percent unidentified species	2.7	-56	-64

The decline in the ruffed grouse population suggested by the summer inventory was very prominent in harvest statistics. In fact it appears that a substantial "crash" in the ruffed grouse population occurred between 1972 and 1973. The reason is not clearly evident. Blue grouse numbers evidently increased substantially.

Total forest grouse hunters and hunter-days increased but the total ruffed grouse harvest declined by 65 percent. Hunter success dropped about 70 percent. The blue grouse harvest almost doubled while blue grouse hunter success increased by about two-thirds over 1972. The total result was an increase in total grouse harvested to a record level; due to increased hunting pressure, and slight decrease in hunter success per day. Success for the season was similar to 1972. Blue grouse comprised over 80 percent of the total harvest compared to an average of 44 percent.

The long-term trend of forest grouse harvest statistics is shown in Figure 1.

Field Bag Checks

A summary of field bag check data for 1973 is found in Table 15. Hunter success trends determined via this method since 1966 are shown in Table 16. Results of the 1973 survey compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Total hunters checked	1,408	-6	+58
Total hours hunted	5,801	-12	+70
Forest grouse per hunter (complete hunts)	0.80	-16	+4
Forest grouse bagged per 100 hours	19	-5	-10
Average hours per hunter-day (complete hunts)	4.3	-9	+10
Hours hunted per grouse bagged	5.4	+8	+6

Field bag checks reflected the decreased hunter success shown by questionnaire data. The average forest grouse hunter spent slightly less time afield each day and more time was required to bag one grouse.

Forest grouse bagged per hunter and per hunter-day.

82

# **QUAIL**

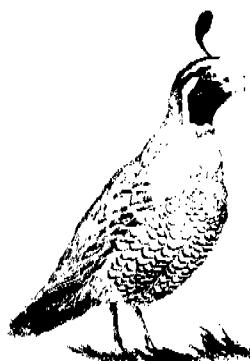

## **SUMMARY**

Quail inventory data indicated a low population level for 1973; a result of poor production in 1972 plus unusually severe winter weather during the 1972-73 winter.

Production in 1973 improved over 1972 to just below average. No Gambel's quail brood data was obtained from southern counties but considering excellent forage conditions, it should have been good.

The total quail harvest decreased due to decreased hunters and hunter days afield. statewide hunter success indexes increased primarily due to increases in the Northeastern, Southeastern and Southern regions. Success in the Northern and Central regions was lower than 1972. Harvest data showed an increased population of Gambel's quail.

Daily bag and possession limits were reduced from 8 and 16 to 5 and 10 respectively for the 1973 season. This probably accounted for some of the decreased hunting pressure.

Brood Counts

Results of the annual random brood survey for 1973 are shown in Table 1 of this section. Long-term trends of young-adult ratios, mean brood size and quail observed per 100 hours are shown in Tables 2-4. Survey results for 1973 compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total quail observed	363	-62	-73
Young per 100 adults	216	+26	-6
Mean brood size	7.04	-2	-1
Quail observed per 100 hours	336	-49	-58
Total hours effort	108	-28	-38

Harvest data for 1972 indicates a breeding population level for 1973 which was lower than that in 1972. Winter mortality was probably greater than normal.

Total effort on quail brood counts was well below both 1972 and the average as was the number of quail observed. Quail observed per 100 hours was also low.

Young per 100 adults increased over 1972 but was still below average while the mean brood size was about average. The fall population level was probably lower than in 1972, except for the Gambel's quail in southern counties where an increased population was expected.

Harvest

Results of the annual hunter questionnaire for 1973 are shown in Table 5. Long-term trends of quail bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county are found in Tables 6-8 and total statewide harvest statistics in Table 9.

The 1973 season compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Quail hunters	5,654	-23	-28
Quail harvested	14,324	-13	-39
Hunter-days afield	17,777	-18	-8
Quail per hunter	2.53	+13	-14
Quail per hunter-day	0.81	+7	-34

Total hunters in 1973 declined from both 1972 and the average as did the number of hunter-days. Total harvest decreased due to reduced pressure while hunter success increased over 1972 but was still well below average.

Hunter success for Gambel's quail in Washington County improved over 1972 but was still lower than in an average year.

Long-term quail harvest statistics are shown in Figure 1.

Gambel's Quail Studies

Annual call-count surveys, long-period waterhole counts and vegetative surveys have been conducted on the west slope of the Beaver Dam Mountains since 1962. Trends of those surveys are shown in Tables 10-12.

Call-counts showed decreased quail abundance compared to 1972, with the population at a low level. No quail were observed during waterhole counts.

Vegetative surveys designed to measure the relative abundance of annual forbs, using filaree (Erodium cicutarium) as the indicator species showed good forb production. Plant density was the highest since 1969 and individual filaree plants attained a size not seen since prior to 1960. Improvement was the result of the relatively severe winter and high moisture level of the winter of 1972-73.

Although no broods were counted markedly improved production was expected. Harvest statistics for Washington County indicated an increased population.

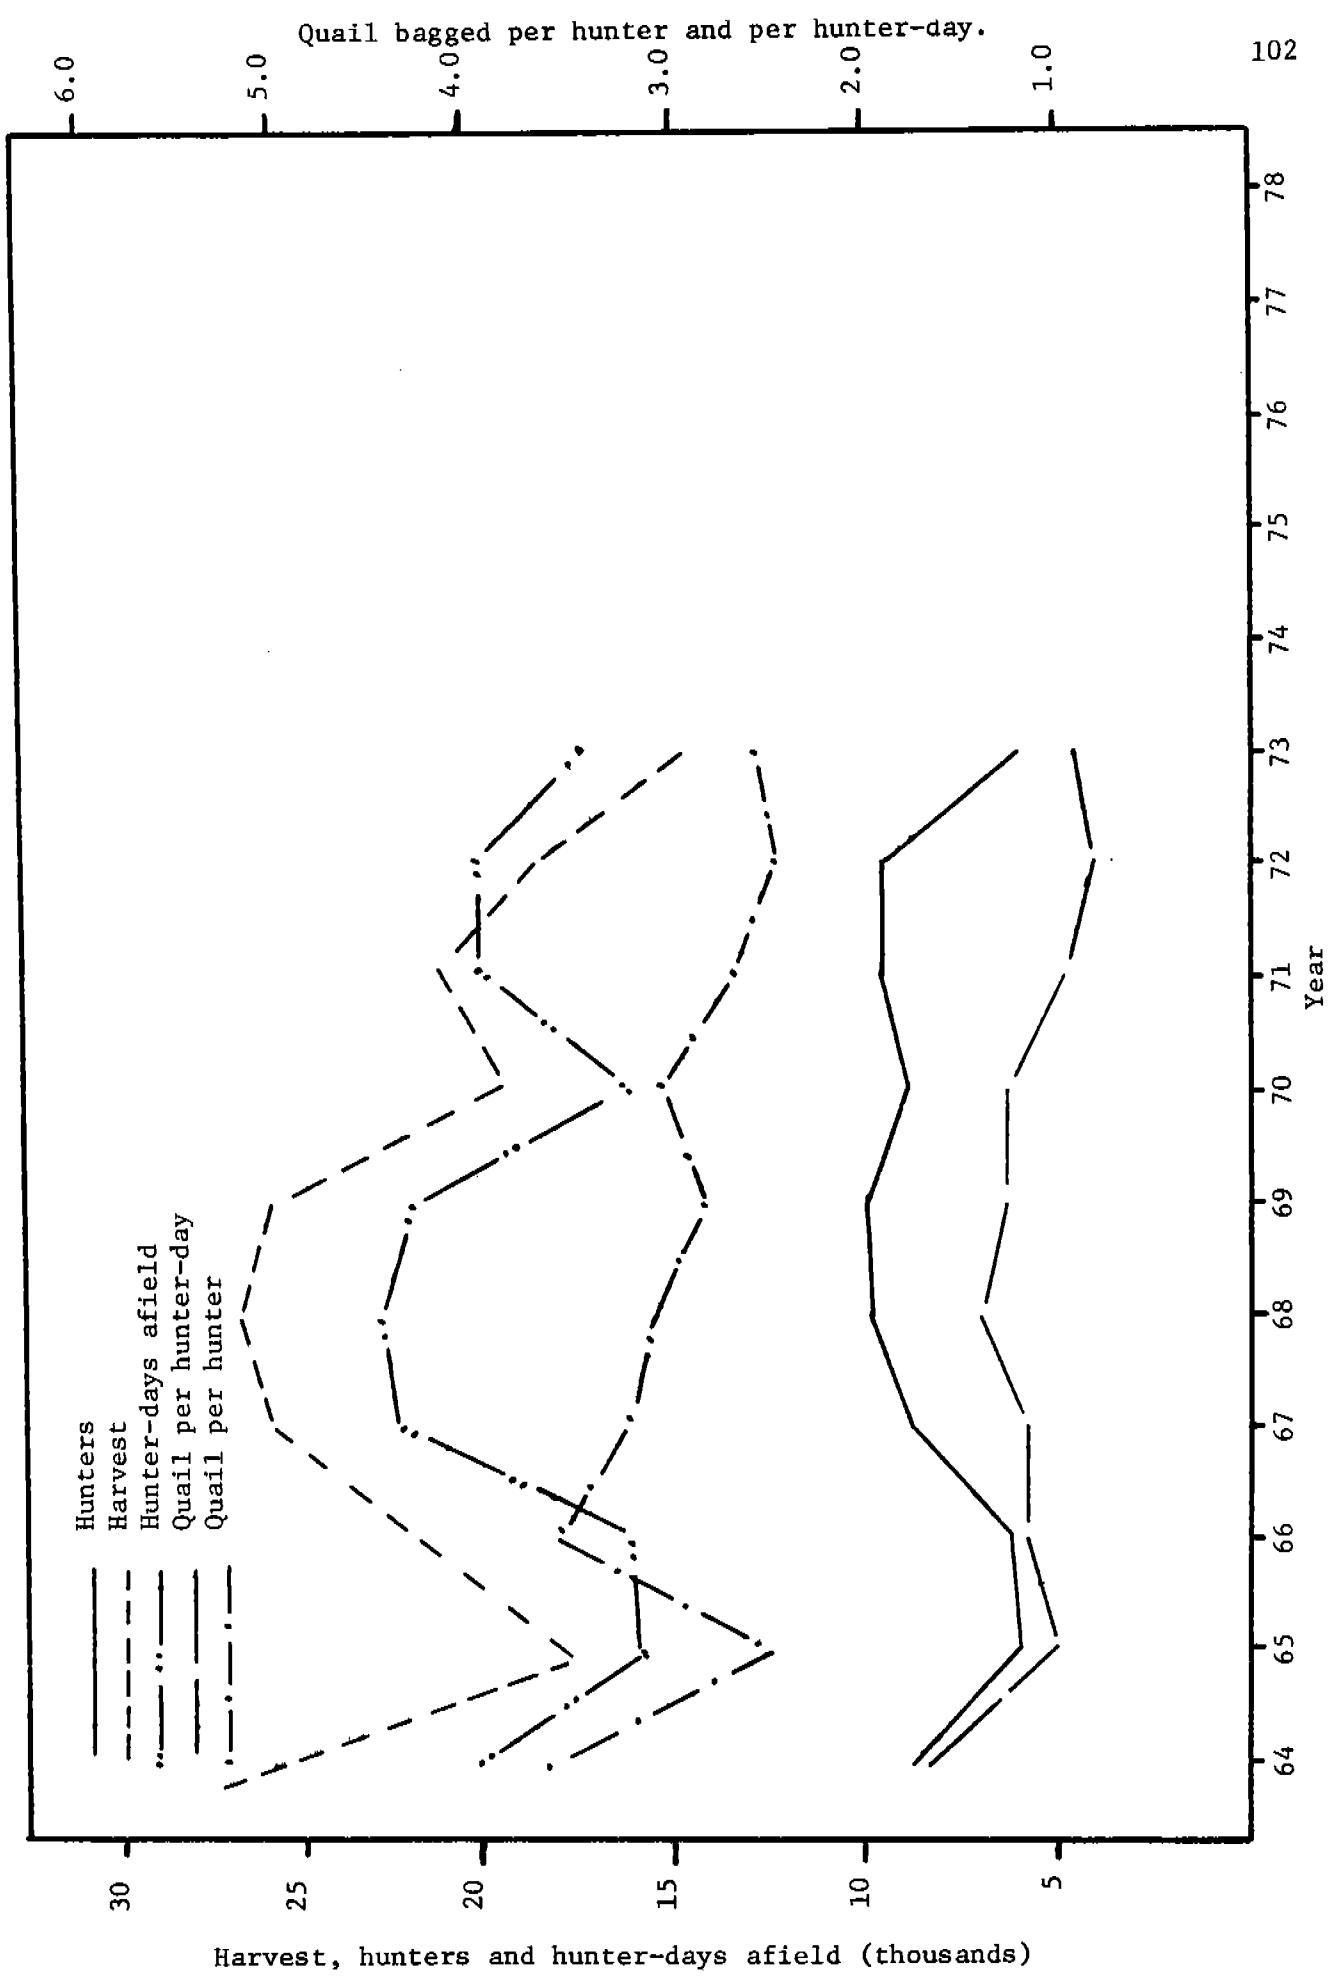

Figure 1. Statewide trend of quail harvest statistics.

# HUNGARIAN PARTRIDGE

## SUMMARY

Harvest statistics for 1972 indicated a decreased breeding population level for 1973. Additionally, some winter loss was reported in Box Elder County due to the relatively severe winter.

Sample sizes of brood data were too low to be very accurate but it seemed evident that production markedly improved. Probably a response to improved forage conditions. It was questionable whether production was sufficient to offset the low breeding population.

Total hunters and harvest decreased to the lowest level since the early 1960's. Hunter success statewide was less than 1972 but in the primary range was comparable to or better than 1972.

Daily bag and possession limits were reduced from 8 and 16 respectively to 5 and 10 for the 1973 season, probably stimulating decreased hunting pressure.

S

### Brood Counts

Results of the annual random brood counts for 1973 are shown in Table 1 of this section. Long-term trends of young-adult ratios, mean brood size and Huns observed per 100 hours are shown in Tables 2-4. Results of this survey for 1973 compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total Huns observed	176	-9	-55
Young per 100 adults	552	+30	+22
Mean brood size	9.75	-6	+6
Huns observed per 100 hours	100	-21	-64
Total hours effort	160	+14	+23

Harvest data for 1972 indicated a decreased breeding population level. Additionally, considering the relatively severe winter increase in winter mortality was probable.

Although total hours effort on brood counts increased slightly in 1973 the total Huns observed and number observed per 100 hours decreased. Indicated production, based on samll sample, was well above both 1972 and the average. Because of the improved production, a fall population comparable to 1972 was expected.

### Harvest

#### Hunter Questionnaire

Results of the annual hunter questionnaire for 1973 are shown in Table 5. Long-term trends of Huns bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county are found in Tables 6-8 and total State-wide harvest statistics in Table 9. The 1973 season compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Hungarian partridge hunters	3,566	-25	-19
Hungarian partridge harvest	6,014	-18	-41
Hunter-days afield	11,516	-5	+7
Huns per hunter	1.69	+10	-24
Huns per hunter-day	0.52	-13	-43

Total hunters decreased to the lowest level since 1962; consequently, total harvest was at the lowest level since 1961. Hunter success per day was down slightly from 1972 and well below average but success per hunter for the season increased over 1972 but was below average. It should be noted that hunter success in the primary range of Box Elder, Cache, Morgan and Wasatch counties was generally, except for Morgan, equal to or better than 1972.

Long-term trends of Hungarian partridge harvest statistics are shown in Figure 1 of this section.

Field Bag Checks

Results of this survey for 1973 are shown in Table 10. Hunter success trends determined via this method are shown in Table 11. Indexes obtained for 1973 compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total hunters checked	101	-26	-54
Total hours hunted	476	-22	-54
Huns per hunter (complete hunts)	0.74	-1	+3
Huns bagged per 100 hours	12	-29	-20
Average hours per hunter-day (complete hunts)	5.4	+26	+10
Hours hunted per Hun bagged	7.4	+23	+9

Field bag check data was compiled primarily in Box Elder County and is indicative of hunter success only in that area. Fewer hunters were checked. Hunter success was similar to 1972. The average hunter spent more hours per day with more hours required to bag one Hun.

Hungarian partridge bagged per hunter and per hunter-day.

116

# **WILD TURKEY**

## **SUMMARY**

Harvest data for 1972 indicated poor reproduction in 1972 and a decreased breeding population in 1973. Extremely severe winter weather in the winter of 1972-73 probably further depressed the breeding population level. It is probable the production in 1973 was also low because of the late spring.

Spring turkey hunters were fewer in number than in 1972 because of weather related poor access and low hunter success in the fall of 1972. Hunters generally had difficulty getting to turkey areas and consequently no turkeys were bagged. Turkey observations were well below previous years as well.

No hunting season was held in the fall of 1973.

Brood Counts

Annual random brood counts have been conducted each year since the introduction of turkeys into Utah in the early 1950's; however, success in finding broods has usually been poor. Sample sizes have generally been too low to meaningfully indicate relative density or production from year to year. During 1973 there were no turkey observations reported.

HarvestSpring Gobbler Seasons

Results of the 1973 spring season are shown in Table 1 of this section. The trend of these data since the first season in 1967 is shown in Table 2. The 1973 spring season compared to 1972 and the average as follows:

	<u>1973</u>	<u>Percent change from 1972</u>	<u>Average</u>
Permits sold	150	-47	-34
Hunters afield	135	-50	-38
Turkeys harvested	0	-100	-100
Hunter-days afield	311	-59	-44
Percent hunter success	0	-100	-100
Turkeys bagged per hunter-day	0.00	-100	-100
Percent of hunters who observed turkeys	10	-74	-75
Total turkeys reported observed	55	-81	-80
Crippling loss (loss:100 bagged)	0	-100	-100

Fall harvest statistics for 1972 reflected apparent poor reproduction in 1972 and indicated a decreased breeding population for 1973. Extremely severe winter weather during the winter of 1972-73 persisted until late spring. During the spring turkey season hunter access to turkey habitat was poor. This, in combination with the poor success of the previous fall, discouraged hunters and resulted in a 50 percent reduction in hunters afield and 59 percent fewer hunter-days. It also resulted in no turkeys harvested. The most common complaint received from hunters on the questionnaire was poor access.

Fall Seasons

No wild turkey hunting season was held in 1973. Harvest trends for prior years are shown in Tables 3-8.

The closed season was based on low population levels in most hunting areas. Low populations were the result of extreme weather conditions and attendant poor reproduction during 1972 and 1973.

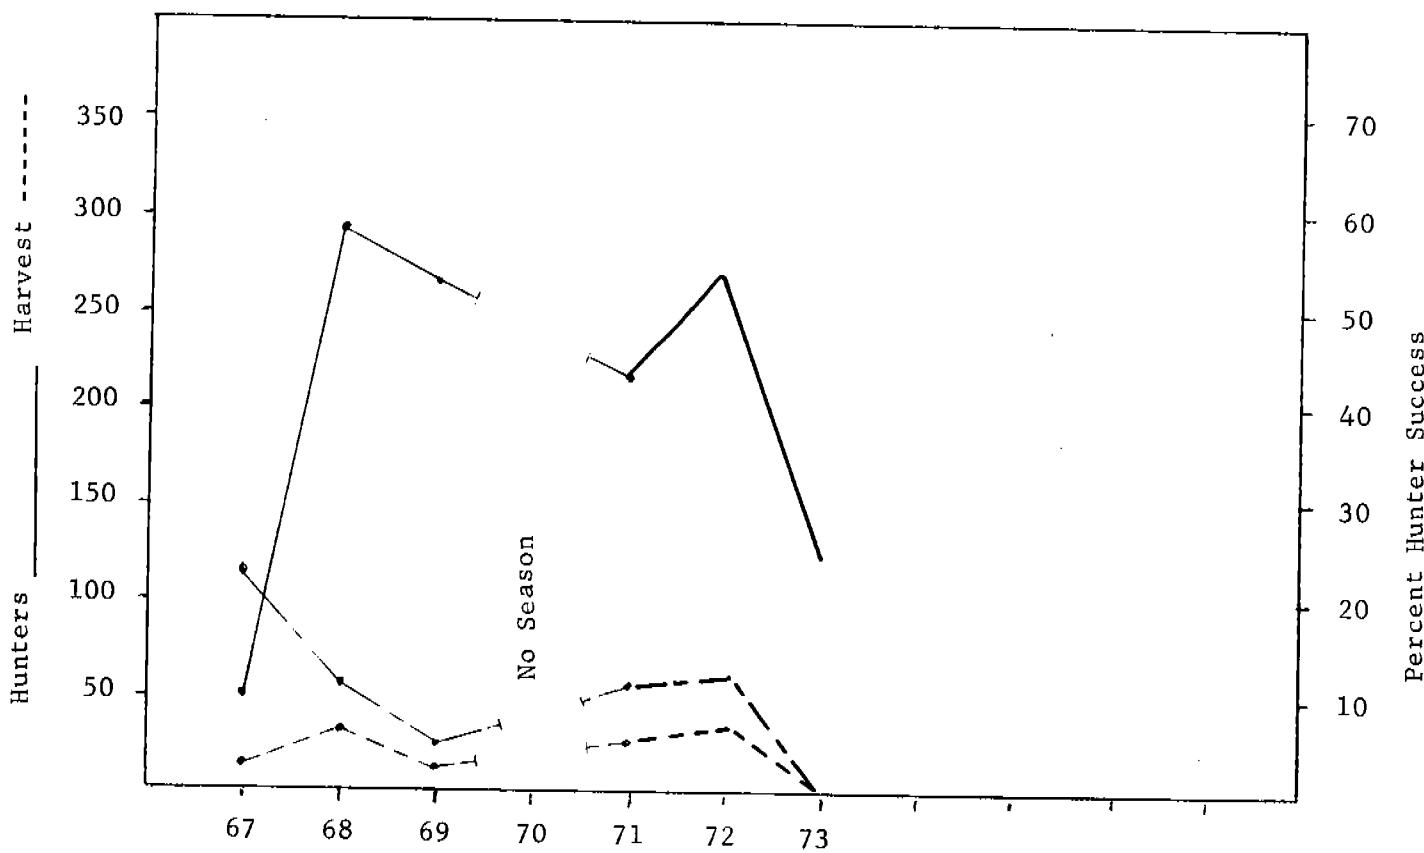

Figure 1. Wild turkey gobbler harvest trends for spring seasons.

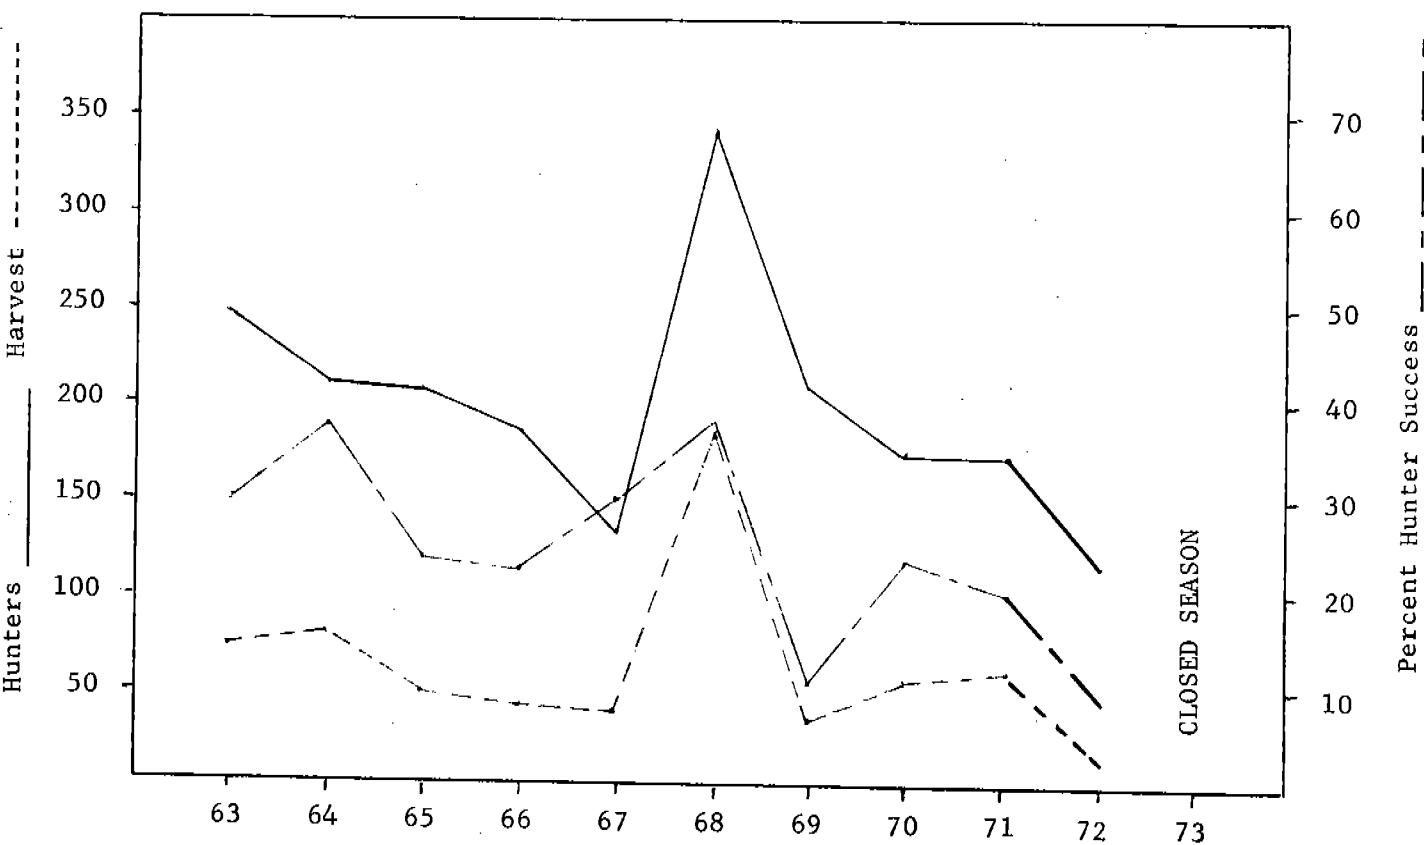

Figure 2. Wild turkey harvest trends for fall seasons.

Percent of hunters who observed turkeys	48	60	29	36	48	54	17	31	28	21		37

\*Data for 1963 collected by hunter checking stations, for 1964 and later via mailed questionnaire.

\*\*During 1966, 1968 and later years some hunters hunted more than one area or failed to designate areas hunted. This accounts for the difference between totals given above and combined tables of separate units in Tables 5, 6, and 7.

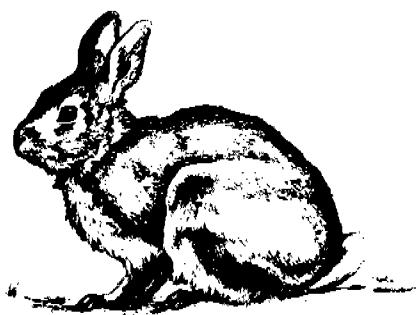

\*\*\*During 1968 the Boulder Mountain and East Zion units had two-bird season limits and the LaSal Mountain a one-bird limit; in 1969 and later years all areas had a two-bird limit. Hunter success was based on the number of successful hunters rather than total turkeys bagged.

# **COTTONTAIL RABBIT**

## **SUMMARY**

Harvest data for 1972 suggested a breeding population for 1973 which was lower than in 1972. Roadside counts indicated a population in 1973 considerably below 1972. Production was also lower than in 1972.

During the 1973 hunting season a marked reduction in total hunters, hunter-days, harvest and hunter-success was evident. This was the second year in a row showing a decline. This decline was attributed to reduced abundance resulting from two years of below normal reproductive success.

### Roadside Counts

Results of the annual roadside counts for 1973 are shown in Table 1 of this section. The trend of cottontails observed per mile and young per 100 adults since 1967 is shown in Tables 2 and 3 respectively. Indexes for 1973 compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total cottontails counted	361	-68	-66
Total miles driven	1,968	-26	-26
Cottontails observed per mile	0.18	-58	-56
Young observed per 100 adules	86	-13	-19

Harvest statistics for 1972 indicated a decreased breeding population for 1973. Severe winter weather during the 1972-73 winter probably resulted in greater than normal winter mortality. Production was probably adversely affected by the late spring.

Roadside count data shows a substantial decline in population density from both 1972 and the average as well as reduced production. There is little doubt that fall populations were at a low level.

### Harvest

#### Hunter Questionnaire

Results of the 1973 hunter questionnaire are found in Table 4. Trends of cottontails bagged per hunter-day, percent of harvest and percent of pressure (hunter-days) by county since 1967 are found in Tables 5-7. Monthly distribution of harvest and hunting pressure each year since 1967 is shown in Table 8. Trend of statewide harvest statistics is found in Table 9 and Figure 2. The 1973 season compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Cottontail hunters	20,109	-12	-24
Cottontail harvest	88,603	-43	-55
Hunter-days afield	87,036	-18	-21
Cottontails per hunter	4.41	-30	-44
Cottontails per hunter-day	1.02	-35	-41

Total hunters, hunter-days afield, harvest and hunter success all declined from both 1972 and the average, probably as a result of a low breeding population and below normal production. Fall populations were undoubtedly at a low level.

The monthly distribution of harvest and hunting pressure were generally similar to previous years; however, pressure seemed to tail off the latter part of the season. This was a result of poor success.

Field Bag Checks

Results of this survey for 1973 are shown in Table 10. Trend of hunter success as determined by bag checks are shown in Table 11. The 1973 season compared to 1972 and the average as follows:

		<u>Percent change from</u>	
	<u>1973</u>	<u>1972</u>	<u>Average</u>
Total hunters checked	196	-26	-60
Total hours hunted	499	-43	-62
Cottontails per hunter (complete hunts)	2.15	-5.3	+26
Cottontails bagged per 100 hours	77	+33	+48
Hours per hunter-day (complete hunts)	2.5	-26	-22
Hours per cottontail bagged	1.2	-29	-45

Results of this survey suggest hunter success at least comparable to 1972; however, most of these data were compiled in the northeastern and southeastern regions, where success is generally higher, and are not comparable on a statewide basis.

The average hunter contacted spent less time afield per day than in 1972 with less time required to bag a cottontail.
